CPEN 400Q Lecture 16
Order finding and Shor's algorithm

Wednesday 6 March 2024

Announcements

- Technical assignment 3 available later this week
- Midterm checkpoint meetings on Thurs/Fri

Last time

We dug into the details of **quantum phase estimation**, which estimates the eigenvalues of unitary matrices.

Learning outcomes

- Use QPE to implement the order finding algorithm
- Implement Shor's algorithm in PennyLane

Order finding on a quantum computer

We defined a function

The *order* of a is the smallest m such that

Order finding on a quantum computer

More formally, define

Define a unitary operation that performs

If m is the order of a, and we apply $U_{N,a}$ m times,

So m is also the order of $U_{N,a}$! We can find it efficiently using a quantum computer.

Let U be an operator and $|\phi\rangle$ any state. How do we find the minimum r such that

QPE does the trick if we set things up in a clever way:

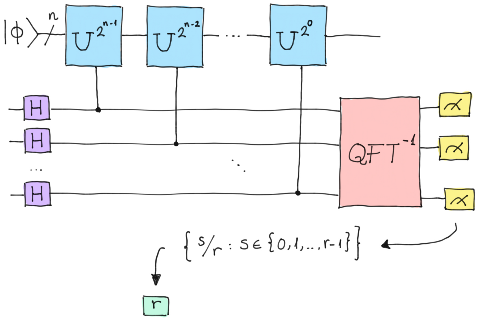

Image credit: Xanadu Quantum Codebook node S.3

Consider the state

If we apply U to this:

Now consider the state

If we apply U to this:

Order finding on a quantum computer

This generalizes to $|\Psi_s\rangle$

It has eigenvalue

Idea: if we can create *any* one of these $|\Psi_s\rangle$, we could run QPE and get an estimate for s/r, and then recover r.

Order finding on a quantum computer

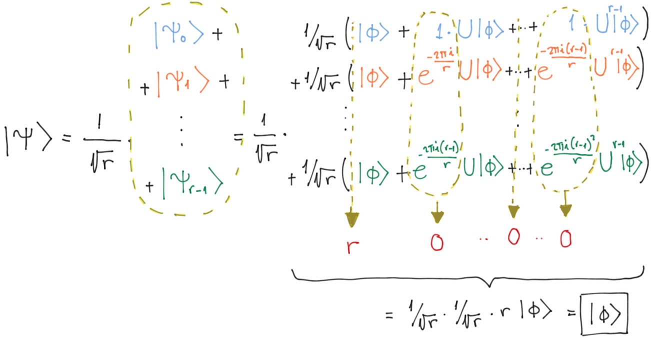
Problem: to construct any $|\Psi_s\rangle$, we would need to know r in advance!

Solution: construct the uniform superposition of all of them.

But what does this equal?

Order finding on a quantum computer

The superposition of all $|\Psi_s\rangle$ is just our original state $|\phi\rangle$!



If we run QPE, the output will be s/r for one of these states.

Shor's algorithm

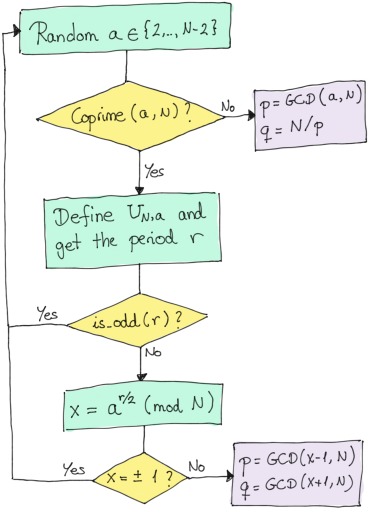

Image credit: Xanadu Quantum Codebook node S.4

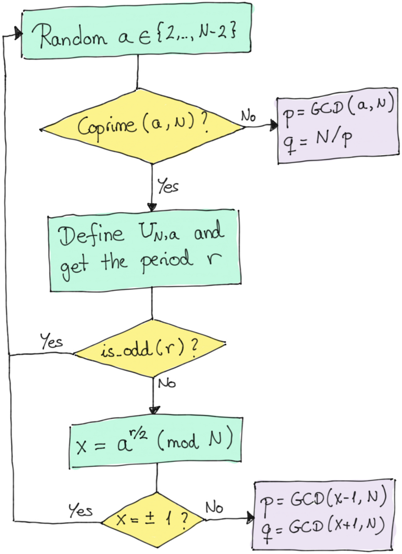
Shor's algorithm can factor a number N like

where p, q are prime.

A quantum computer runs order finding to obtain p and q.

Everything else is number theory.



Non-trivial square roots

Idea: find a *non-trivial square root* of N, i.e., some $x \neq \pm 1$ s.t.

If we find such an x,

Then

for some integer k.

Non-trivial square roots

If

then $x - 1$ is a multiple of one of p or q, and $x + 1$ is a multiple of the other.

We can compute p and q by finding their *gcd* with N:

Non-trivial square roots and factoring

It's actually okay to find any *even* power of x for which this holds:

We can use order finding to find such an r. If it is even, we can obtain x and factor N.

Shor's algorithm

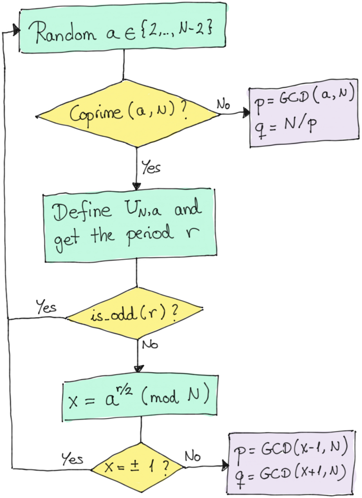


Image credit: Xanadu Quantum Codebook node S.4

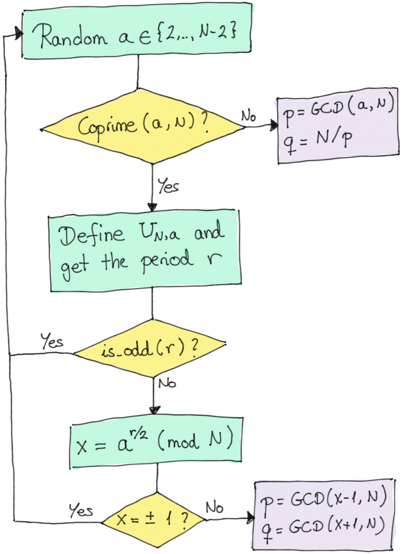
Is this really efficient?

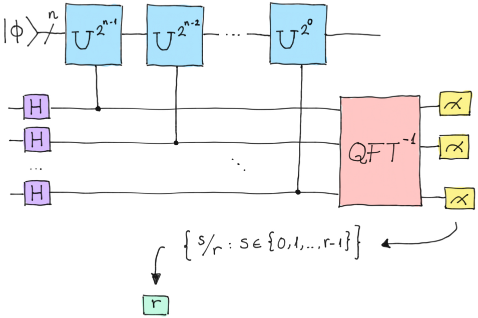
GCD: polynomial w/Euclid's algorithm

Modular exponentiation: can use exponentiation by squaring, other methods to reduce operations and memory required



Is this really efficient?

Quantum part: let $L = \lceil \log_2 N \rceil$.



QFT: polynomial in number of qubits $O(L^2)$

Controlled-U gates: implemented using something called *modular exponentiation* in $O(L^3)$ gates.

Discussion

Form groups of 3-4, and consider the following questions:

1. Shor's algorithm was developed in 1994. Estimate the fraction of today's world population that can actually implement it.
2. Shor's algo can be used to break cryptosystems like RSA. Estimate the proportion of the world that would be affected if someone actually deployed it at scale.
3. Is it ethical to develop such an algorithm? Is it ethical to *teach* such an algorithm?
4. Look up some resource estimates; how long would it actually take to break 2048-bit RSA? How many qubits are needed?
5. Think critically about (a) who knows how to implement the algorithm, and (b) who will potentially have access to quantum hardware in the future. What issues can you foresee?
6. What are ways we can keep our cryptographic infrastructure secure in the future?

Next time

Content:

- Hands-on with quantum key distribution

Action items:

1. Midterm checkpoint meetings
